Lecture 2

Lecturer: Asst. Prof. M. Mert Ankarali

Big Picture of EE402

In this course, the main focus will be on continuous-time systems that are controlled (sampled and actuated) by a digital computer interface. Such a discrete-time control system consists of four major parts as illustrated in Fig. 2.2,

- 1. The plant is a continuous-time dynamical system
- 2. Analog-to-Digital Converter (ADC)
- 3. Controller (μP) , a microprocessor/microcontroller with a "real-time" OS
- 4. Digital-to-Analog Converter (DAC)

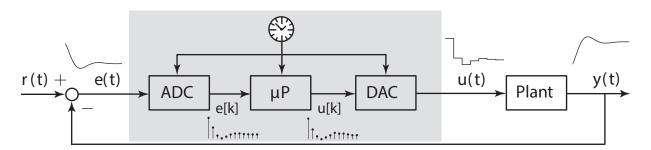

Figure 2.1: Block diagram of a digital control system

Most of the time, the plant is modeled as a "smooth" continuous dynamical system. In this course, we will focus on LTI systems. Rhus, we will assume that (unless otherwise is given), the plant is a continuous LTI plant model with a transfer function of $G_c(s)$ for which both the input and output are continuous time signals.

The "digital" blocks inside the closed-loop block diagram structure are ADC, the Controller, and DAC. It is generally assumed (design requirement) that all blocks shares a common "hard real time" clock.

A general ADC is a device that converts an analog signal to a digital signal. In this course, we will model the ADC block as an *ideal sampler* for which the input is a continious-time signal, e(t), and the output is a discrete-time signal, e[k], where the relation between the continuous- and discrete-time signals are given as

$$e(kT) = e[k], \ k \in \mathbb{Z}^+,$$

where constant T is the sampling time.

The microcontroller/microprocessor processes some set of digital input signals to produce some set of digital output signals. The outputs are defined at only some specified instances defined by the real-time clock. In

2-2 Lecture 2

this course, we will model the μP block as an ideal discrete-time LTI system for which both the input and output are discrete-time signals, with a transfer function of $G_c(z)$.

The DAC is a device that converts a digital signal to an analog signal. In this course we assume that it is an ideal *Hold* element for which the input signal is a discrete-time signal, where as output is a continuous-time signal. The most commonly used *Hold* system is ZOH (Zero-Order-Hold) which is a mapping defined by the following relation

$$u(t) = u[k], \text{ for } t \in [kT, (k+1)T)$$

Higher-order holds available but seldom used.

The idealized and simplified block-diagram structure is given in Fig.

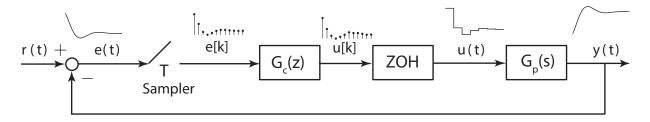

Figure 2.2: Block diagram of an LTI discrete-time control system

Major challenge: Loop contains both continuous-time and discrete-time parts.

Sampling

Fig. 2.3 illustrates two different ideal sampler (both of them will be covered in this course. Firs column is an *impulse sampler* for which the output is a continuous signal but it is composed of trains of impulses (impulse train). Second one is an ideal complete CT-to-DT sampler which convertes the impulse train into DT sequence.

The output of the impulse sampler, x * (t), can be represented with the following infinite summations

$$x^*(t) = \sum_{k=0}^{\infty} x(kT)\delta(t - kT) = \sum_{k=0}^{\infty} x[k]\delta(t - kT)$$
 or
$$x^*(t) = x(0)\delta(t) + x(T)\delta(t - T) + \dots + x(kT)\delta(t - kT) + \dots$$
$$= x[0]\delta(t) + x[1]\delta(t - T) + \dots + x[k]\delta(t - kT) + \dots$$

Now let's consider the Laplace transform of $x^*(t)$

$$X^{*}(s) = \mathcal{L}\{x^{*}(t)\} = \mathcal{L}\left\{\sum_{k=0}^{\infty} x(kT)\delta(t-kT)\right\} = \sum_{k=0}^{\infty} x(kT)\mathcal{L}\left\{\delta(t-kT)\right\}$$
$$= \sum_{k=0}^{\infty} x(kT) \int_{t=0}^{\infty} \delta(t-kT)e^{-st}dt = \sum_{k=0}^{\infty} x(kT)e^{-skT} = \sum_{k=0}^{\infty} x[k]e^{-skT}$$

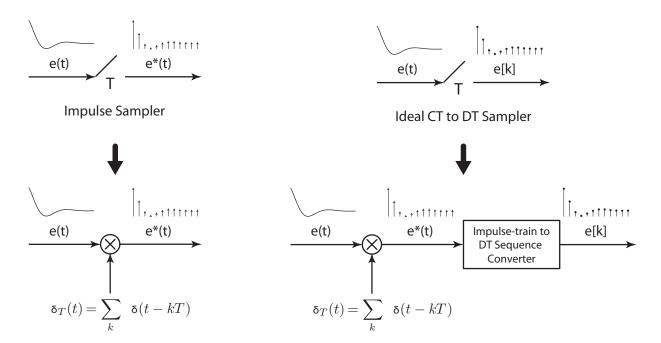

Figure 2.3: Two different ideal samplers

Now let's define a map in complex domain such that

$$z = e^{Ts}$$
 or $s = \frac{1}{T} \ln z$

Then we have

$$X^*(s)|_{s=(1/T)lnz} = \sum_{k=0}^{\infty} x[k]z^{-k}$$

where

$$X(z)=\mathcal{Z}\{x[k]\}=\sum_{k=0}^{\infty}x[k]z^{-k}$$

Z-transform

Z-transform of a (causal) discrete time signal x[k] is given by

$$X(z) = \mathcal{Z}\{x[k]\} = \sum_{k=0}^{\infty} x[k]z^{-k}$$

If x[k] is a sampled signal from a continuous time signal x(t) with a sampling time of T, we (abuse of notation) also use the following notation

$$X(z) = \mathcal{Z}\{x(kT)\} = \mathcal{Z}\{x^*(t)\}$$

2-4 Lecture 2

Z-transforms of elementary functions

We assume that all signals are causal thus $t \in \mathbb{R}^+$ and $k \in \mathbb{Z}^+$

Unit-step function x(t) = 1 and thus x(kT) = x[k] = 1, the Z-transform is given by

$$X(z) = \sum_{k=0}^{\infty} z^{-k} = \frac{1}{1 - z^{-1}} = \frac{z}{z - 1}$$

Unit-ramp function x(t) = t and thus x(kT) = x[k] = kT, the Z-transform is given by

$$X(z) = \sum_{k=0}^{\infty} kTz^{-k} = T(z^{-1} + 2z^{-2} + 3z^{-3} + \cdots) = Tz(z^{-2} + 2z^{-3} + 3z^{-4} + \cdots)$$

$$= Tz\frac{d}{dz}\left(\int (z^{-2} + 2z^{-3} + 3z^{-4} + \cdots)dz\right) = Tz\frac{d}{dz}\left(-(z^{-1} + z^{-2} + z^{-3} + \cdots)\right)$$

$$= Tz\frac{d}{dz}\left(\frac{-1}{z-1}\right) = \frac{Tz}{(z-1)^2} = \frac{Tz^{-1}}{(1-z^{-1})^2}$$

Exponential sequence $x[k] = a^k$

$$X(z) = \sum_{k=0}^{\infty} a^k z^{-k} = \sum_{k=0}^{\infty} \left(\frac{z}{a}\right)^{-k} = \frac{1}{1 - az^{-1}} = \frac{z}{z - a}$$

Exponential function $x(t) = e^{bt}$ and thus $x(kT) = x(k) = e^{bTk}$

$$X(z) = \sum_{k=0}^{\infty} e^{bTk} z^{-k} = \sum_{k=0}^{\infty} (e^{bT})^k z^{-k} = \frac{1}{1 - e^{bT} z^{-1}} = \frac{z}{z - e^{bT}}$$

Cosine function $x(t) = \cos(\omega t)$, and thus $x(kT) = x(k) = \cos(\omega T k)$

$$\begin{aligned} \cos(\omega T k) &= \frac{1}{2} \left(e^{j\omega T k} + e^{-j\omega T k} \right) X(z) = \frac{1}{2} \left(\frac{z}{z - e^{j\omega T}} + \frac{z}{z - e^{-j\omega T}} \right) = \frac{1}{2} \frac{z(z - e^{-j\omega T}) + z(z - e^{j\omega T})}{(z - e^{-j\omega T})(z - e^{j\omega T})} \\ &= \frac{1}{2} \frac{2z^2 - z(e^{-j\omega T} + e^{j\omega T})}{z^2 - z(e^{-j\omega T} + e^{j\omega T}) + 1} = \frac{z^2 - z\cos(\omega T)}{z^2 - z2\cos(\omega T) + 1} \\ &= \frac{1 - z^{-1}\cos(\omega T)}{1 - z^{-1}2\cos(\omega T) + z^{-2}} \end{aligned}$$

Properties and Theorems of the Z-transform

Linearity

$$x(k) = \alpha f(k) + \beta g(k) \rightarrow X(z) = \alpha F(z) + \beta G(z), \forall \alpha, \beta, f(k), \& g(k)$$

Multiplication by a^k

$$\mathcal{Z}\{a^k x[k]\} = \sum_{k=0}^{\infty} a^k x[k] z^{-k} = \sum_{k=0}^{\infty} x[k] (z/a)^{-k}$$
$$\mathcal{Z}\{a^k x[k]\} = X(z/a)$$

Complex translation theorem Let $y(t) = e^{-at}x(t)$ and $X(z) = \ddagger \{x(kT)\}$, then

$$\mathcal{Z}\{y(kT)\} = \mathcal{Z}\{e^{-aTk}x(kT)\} = X(e^{aT}z)$$

Shifting theorem Let x(t) be a causal CT signal, thus we have x(t) = 0 for t < 0. Similarly sampled DT signal has the property x[nk] = 0 for k < 0. For the sake of simplicity lets work on the sampled (i.e. DT) signal. Let

$$\mathcal{Z}\{x^*(t)\} = \mathcal{Z}\{x[k]\} = X(z)$$

Shifting right by N (Causal shifting): Let y[k] = x[k-N], then

$$\mathcal{Z}\{y[k]\} = \sum_{k=0}^{\infty} y[k]z^{-k} = \sum_{k=0}^{\infty} x[k-N]z^{-k} = \sum_{k=N}^{\infty} x[k-N]z^{-k}$$

Let k = m + N then

$$\mathcal{Z}\{y[k]\} = \sum_{m=0}^{\infty} x[m]z^{-(m+N)} = z^{-N} \sum_{m=0}^{\infty} x[m]z^{-m}$$

$$\mathcal{Z}\{x[k-N]\} = z^{-N}X(z)$$

Shifting left by N (Non-causal shifting) & Bilateral Z transform: Let y[k] = x[k+N],

$$\mathcal{Z}\{x[k+N]\} = \sum_{k=-\infty}^{\infty} x[k+N]z^{-k} = \sum_{m=-\infty}^{\infty} x[m]z^{-(m-N)} = z^{N} \sum_{m=-\infty}^{\infty} x[m]z^{-m}$$

$$\mathcal{Z}\{x[k+N]\} = z^{N}X(z)$$

Shifting left by N (Non-causal shifting) & Unilateral Z transform: Let y[k] = x[k+N],

$$\mathcal{Z}\{x[k+N]\} = \sum_{k=0}^{\infty} x[k+N]z^{-k}$$

Let k = m - N then

$$\mathcal{Z}\{x[k+N]\} = \sum_{m=N}^{\infty} x[m]z^{-(m-N)} = z^N \sum_{m=N}^{\infty} x[m]z^{-m} = z^N \left(\sum_{k=0}^{\infty} x[k]z^{-k} - \sum_{k=0}^{N-1} x[k]z^{-k}\right)$$

$$\mathcal{Z}\{x[k+N]\} = z^N \left(X(z) - \sum_{k=0}^{N-1} x[k]z^{-k}\right)$$

From this equation we can obtain

$$\begin{split} \mathcal{Z}\{x[k+1]\} &= zX(z) - zx[0] \\ \mathcal{Z}\{x[k+2]\} &= z^2X(z) - z^2x[0] - zx[1] \\ &\vdots \end{split}$$

Example 1. Let u[k] be the unit-step function. Compute $\mathcal{Z}\{u[k-1]\}$ both directly and using the shifting property.

$$\mathcal{Z}\{u[k-1]\} = \frac{z^{-1}}{1-z^{-1}}$$

2-6 Lecture 2

Example 2. Let $y[k] = \sum_{n=0}^{k} x[k]$ where $k \in \mathbb{Z}^+$. Compute Y(z) in terms of X(z) using the shifting theorem.

$$Y(z) = \frac{1}{1 - z^{-1}}X(z)$$

Initial Value Theorem Let $X(z) = \mathcal{Z}\{x[n]\}$ and if the following limit exists, then the initial value of x[0] or x(0) is given by

$$x[0] = \lim_{z \to \infty} X(z)$$

Indeed the proof is very easy

$$\lim_{z \to \infty} X(z) = \lim_{z \to \infty} \left[\sum_{k=0}^{\infty} x(k) z^{-k} \right] = \lim_{z \to \infty} \left[x(0) + x(1) z^{-1} + x(2) z^{-2} + \dots \right] = x(0)$$

Final Value Theorem

Let's assume that x(kT) or x[k] is a convergent sequence (DT signal). Then the final value theorem states that

$$\lim_{k \to \infty} x[k] = \lim_{z \to 1} (1 - z^{-1}) X(z)$$

Proof: Let's take the Z transform of x[k] - x[k-1]

$$\mathcal{Z}\{x[k] - x[k-1]\} = \sum_{k=0}^{\infty} (x[k] - x[k-1]) z^{-k}$$

$$X(z) - X(z)z^{-1} = \left(x[0]\left(1 - z^{-1}\right) + x[1]\left(z^{-1} - z^{-2}\right) + x[2]\left(z^{-2} - z^{-3}\right) + x[3]\left(z^{-3} - z^{-4}\right) + \cdots\right) + \lim_{k \to \infty} x[k]z^{-k}$$

$$\lim_{z \to 1} X(z) \left(1 - z^{-1}\right) = (0 + 0 + \cdots) + \lim_{z \to 1} \lim_{k \to \infty} x[k]z^{-k}$$

$$\lim_{z \to 1} X(z) \left(1 - z^{-1}\right) = \lim_{k \to \infty} x[k]$$

Complex Differentiation Theorem

Consider

$$\begin{split} \frac{d}{dz}X(z) &= \frac{d}{dz}\left[\sum_{k=0}^{\infty}x[k]z^{-k}\right] = \sum_{k=0}^{\infty}x[k]\frac{d}{dz}z^{-k} = \sum_{k=0}^{\infty}(-k)x[k]z^{-k-1} \\ &-z\frac{d}{dz}X(z) = \sum_{k=0}^{\infty}kx[k]z^{-k} \\ &-z\frac{d}{dz}X(z) = \mathcal{Z}\{kx[k]\} \end{split}$$

In general

$$(-z)^m \frac{d}{dz^m} X(z) = \mathcal{Z}\{k^m x[k]\}$$

Example 3. Find the Z-transform of the unit ramp function, r[k] = k, $k \in \mathbb{Z}^+$ by applying the Complex Differentiation Theorem to the Z-transform of the unit step function.

Real Convolution Theorem Let f[k] and g[k] are causal signals and associated Z transforms are F(z) and G(z) respectively. The DT convolution operator is defined as

$$f[n] * g[n] = \sum_{k=0}^{n} f[n-k]g[k]$$

Real Convolution Theorem states that

$$\mathcal{Z}\{f[n] * g[n]\} = F(z)G(z)$$

Proof

$$\mathcal{Z}\{f[n] * g[n]\} = \sum_{n=0}^{\infty} \left[\sum_{k=0}^{n} f[n-k]g[k] \right] z^{-n}$$

Since we know that f[m] = 0 for m < 0, we can stretch the upper limit of the sum as

$$\mathcal{Z}\{f[n] * g[n]\} = \sum_{n=0}^{\infty} \left[\sum_{k=0}^{\infty} f[n-k]g[k] \right] z^{-n} = \sum_{k=0}^{\infty} \sum_{n=0}^{\infty} f[n-k]g[k]z^{-n}$$

Let n = m + k then

$$\begin{split} \mathcal{Z}\{f[n]*g[n]\} &= \sum_{k=0}^{\infty} \sum_{m=-k}^{\infty} f[m]g[k]z^{-m}z^{-k} = \sum_{k=0}^{\infty} g[k]z^{-k} \sum_{m=0}^{\infty} f[m]z^{-m} \\ \mathcal{Z}\{f[n]*g[n]\} &= F(z)G(z) \end{split}$$

The Inverse Z-transform

- 1. Direct division method
- 2. Z-tranform tables & partial-fraction expansion
- 3. "Simulation" method
- 4. Inversion integral method

Direct division

Direct division (or long division) method uses the fact that X(z) can be expressed as

$$X(z) = \sum_{k=0}^{\infty} x[k]z^{-k} = x(0) + x(1)z^{-1} + x(2)z^{-2} + x(3)z^{-3} + \cdots$$

The goal is finding the power series expansion of X(z) using the long division approach. Here we assume that X(z) cane be represented as a ratio of two polynomials in z (or z^{-1})

$$X(z) = \frac{b_0 z^m + b_1 z^{m-1} + \dots + b_m}{z^n + a_1 z^{n-1} + \dots + a_n} = \frac{b_0 z^{-n+m} + b_1 z^{-n+m-1} + \dots + b_m z^{-n}}{1 + a_1 z^{-1} + \dots + a_n z^{-n}}$$

2-8 Lecture 2

For the direct division method it is easer to work when the polynomials are written in terms of powers of z^{-1} .

Example 4. Find the inverse Z-transform of $X(z) = \frac{z^{-1}}{1-2z^{-1}+z^{-2}}$.

Thus,

$$X(z) = 0 + 1z^{-1} + 2z^{-2} + 3z^{-3} + 4z^{-4} + \dots$$

$$\downarrow$$

$$x[k] = 0\delta[k] + 1\delta[k-1] + 2\delta[k-2] + 3\delta[k-3] + 4\delta[k-4] + \dots = k$$

Partial Fraction Expansion

In most applications X(z) can be re-written in terms of poles and zeros as

$$X(z) = b_0 \frac{(z - z_1) \cdots (z - z_m)}{(z - p_1) \cdots (z - p_n)} \quad (m \le n)$$

Specific (but extremely common) case

$$\frac{X(z)}{z} = \sum_{i=1}^{n} \frac{a_i}{(z - p_i)}$$

where all poles are distinct and simple order. We can compute each a_i using

$$a_i = \lim_{z \to p_i} \left[(z - p_i) \frac{X(z)}{z} \right]$$

Example 5. Find the inverse Z-transform of $X(z) = \frac{(1-b)z}{(z-1)(z-b)}$. Solution:

$$\frac{X(z)}{z} = \frac{(1-b)}{(z-1)(z-b)} = \frac{a_1}{z-1} + \frac{a_2}{z-b}$$

$$a_1 = \lim_{z \to 1} \left[(z-1) \frac{X(z)}{z} \right] = 1$$

$$a_2 = \lim_{z \to b} \left[(z-b) \frac{X(z)}{z} \right] = -1$$

$$X(z) = \frac{z}{z-1} - \frac{z}{z-b}$$

$$x[k] = 1 - b^k$$

Now let's assume that $\frac{X(z)}{z}$ has double pole at p_1 and all other poles are distinct

$$\frac{X(z)}{z} = \frac{c_1}{z - p_1} + \frac{c_2}{(z - p_1)^2} + \cdots$$

It is easy to show that

$$c_2 = \lim_{z \to p_1} \left[(z - p_1)^2 \frac{X(z)}{z} \right]$$

It is also possible to show that

$$c_1 = \lim_{z \to p_1} \left\{ \frac{d}{dz} \left[(z - p_1)^2 \frac{X(z)}{z} \right] \right\}$$

Example 6. Find the inverse Z-transform $X(z) = \frac{2z^2 - 3z}{(z-1)^2}$. Solution:

$$\frac{X(z)}{z} = \frac{c_1}{z - 1} + \frac{c_2}{(z - 1)^2}$$

$$c_1 = \lim_{z \to 1} \frac{d}{z} \left[(z - 1)^2 \frac{X(z)}{z} \right] = 2$$

$$c_2 = \lim_{z \to 1} \left[(z - 1)^2 \frac{X(z)}{z} \right] = -1$$

$$x[k] = 2 - k$$

Example 7. Find the inverse Z-transform $X(z) = \frac{(1-b)}{(z-1)(z-b)}$. Solution:

$$X(z) = \frac{(1-b)}{(z-1)(z-b)} = \frac{a_1}{z-1} + \frac{a_2}{z-b}$$

$$a_1 = \lim_{z \to 1} [(z-1)X(z)] = 1$$

$$a_2 = \lim_{z \to b} [(z-b)X(z)] = -1$$

$$X(z) = z^{-1} \left(\frac{z}{z-1} - \frac{z}{z-b}\right)$$

$$x[k] = [1-b^{k-1}]u[k-1]$$

2-10 Lecture 2

Example 8. Find the inverse Z-transform $X(z) = \frac{z^2-2}{(z-1)(z-2)}$. Solution:

$$X(z) = \frac{z^2 - 2}{z^2 - 3z + 2} = 1 + \frac{3z - 4}{z^2 - 3z + 2}$$

$$X(z) = 1 + \frac{a_1}{z - 1} + \frac{a_2}{z - 2}$$

$$a_1 = \lim_{z \to 1} [(z - 1)X(z)] = 1$$

$$a_2 = \lim_{z \to 2} [(z - 2)X(z)] = 2$$

$$X(z) = 1 + \frac{1}{z - 1} + \frac{2}{z - 2} = \frac{1}{z - 1} + \frac{z}{z - 2}$$

$$x[k] = 1 + 2^k - \delta[k]$$
